Project Overview

This project focuses on importing structured data from a spreadsheet into a target application using Transform Maps. The approach is intended to reduce manual data entry, improve consistency, and provide a repeatable process for mapping source spreadsheet columns to destination fields.

Problem Statement

Users who maintain data in spreadsheets may need to enter the same information manually into another system. Manual entry can take time and may introduce missing values, formatting differences, or duplicate records. A spreadsheet-based import with a Transform Map provides a structured way to transfer and transform the data.

Objective

To design a simple workflow in which spreadsheet data is prepared, imported into a staging/import table, mapped to the required target fields, transformed where necessary, validated, and then loaded into the target table.

Empathy Map Canvas

The empathy map captures the likely needs, observations, actions, pain points, and desired outcomes of a user who is responsible for importing spreadsheet data.

User Perspective

The user needs a predictable import process with clear field mappings, meaningful validation messages, and a way to identify failed records. The desired outcome is accurate data transfer with less repetitive manual work.

Proposed Solution & Workflow

The following workflow describes how spreadsheet data can be handled using a Transform Map-based import process.

Step	Activity	Expected Result
1	Prepare spreadsheet	Columns are named consistently and required values are filled.
2	Upload spreadsheet	Source data is available for import.
3	Load into import/staging table	Spreadsheet rows become import-set records.
4	Create Transform Map	Source fields are mapped to target fields.
5	Define transformations	Values are cleaned, converted, or defaulted when required.
6	Run transform	Valid records are moved to the target table.
7	Validate results	Inserted/updated records and errors are reviewed.

Example Spreadsheet Structure

Employee ID	Name	Email	Department	Status
EMP001	Arun	arun@example.com	IT	Active
EMP002	Priya	priya@example.com	HR	Active
EMP003	Karthik	karthik@example.com	Finance	Active

Note: The sample values above are illustrative. The actual spreadsheet columns should match the fields required by the target table.

Transform Map Design

A Transform Map defines how fields from the imported spreadsheet are matched to fields in the destination table. The mapping should be designed around the target data model and the business rules required for the import.

Suggested Field Mapping

Source Spreadsheet Field	Target Field	Transformation / Check
Employee ID	Employee ID	Use as unique identifier; check for duplicates.
Name	Name	Trim extra spaces and validate that value is present.
Email	Email	Validate format; reject invalid values.
Department	Department	Map to an existing department value.
Status	Status	Convert source status to the target choice/value if needed.

Validation Checklist

- Confirm the spreadsheet has the expected column headers.
- Check mandatory fields before starting the transform.
- Identify duplicate unique identifiers.
- Validate email/choice/reference values where applicable.
- Review successful, updated, and failed records after the transform.
- Correct failed source rows and repeat the import when required.

Expected Benefits

A structured Transform Map process can support bulk data loading, reduce repetitive manual entry, improve consistency between source and target fields, and make errors easier to identify and correct.

Conclusion

The project applies an empathy-driven approach to a practical data-import problem. By understanding the user's need for speed, accuracy, visibility, and simple error handling, the proposed spreadsheet-to-target workflow provides a clear path for importing data through Transform Maps.
